Heat Effects of Chemical Reactions

Enthalpy change for reactions involving compounds

Enthalpy of formation of a compound at standard conditions is obtained from the literature as standard enthalpy of formation

$$\Delta H^{\circ}_{298}(\text{CO}_2(\text{g})) = -393690 \text{ J/mole at } 298 \text{ K}$$

Elements are assigned 0 enthalpy of formation

Enthalpy of a reaction involving compounds is calculated using Hess' law:

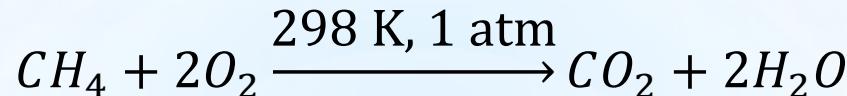

$$\Delta H_{Rxn} = \sum \Delta H_{products} - \sum \Delta H_{reactants}$$

The enthalpy changes are calculated from standard enthalpies of formation if the reaction occurs at standard conditions

$$\sum \Delta H_{products} = \sum H^{\circ}_{298}(products)$$

$$\sum \Delta H_{reactants} = \sum H^{\circ}_{298}(reactants)$$

Consider the chemical reaction:

$$\begin{aligned}\Delta H_{Rxn} &= \Delta H^o_{298} \\ &= (H^o_{298}(CO_2) + 2H^o_{298}(H_2O)) - (H^o_{298}(CH_4) + 2H^o_{298}(O_2))\end{aligned}$$

$$H^o_{298}(CO_2) = \Delta H^o_{298}(CO_2) + H^o_{298}(C) + H^o_{298}(O_2)$$

$$\text{since } \Delta H^o_{298}(CO_2) = H^o_{298}(CO_2) - H^o_{298}(C) + H^o_{298}(O_2)$$

Similarly,

$$H^o_{298}(H_2O) = \Delta H^o_{298}(H_2O) + H^o_{298}(H_2) + \frac{1}{2}H^o_{298}(O_2)$$

$$H^o_{298}(CH_4) = \Delta H^o_{298}(CH_4) + H^o_{298}(C) + 2H^o_{298}(H_2)$$

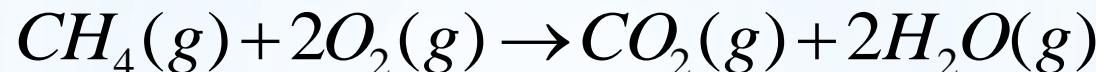

$$\text{So } \Delta H_{Rxn} = \Delta H^o_{298} = \Delta H^o_{298}(CO_2) + 2\Delta H^o_{298}(H_2O) - \Delta H^o_{298}(CH_4)$$

$$\boxed{\Delta H^o_{298} = \sum \Delta H^o_{298}(\text{products}) - \sum \Delta H^o_{298}(\text{reactants})}$$

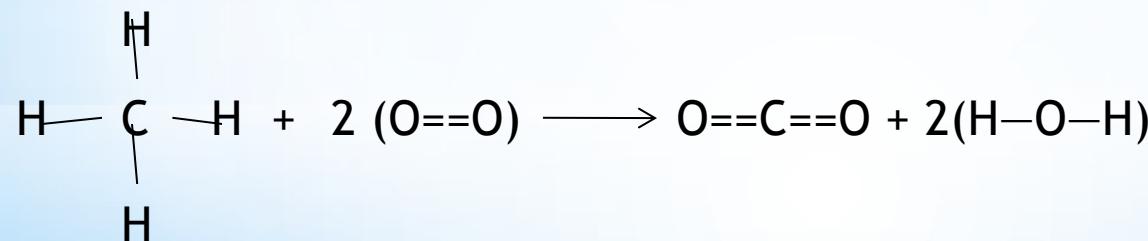

Molecular interpretation of enthalpy change

Enthalpy change of systems involving gaseous compounds may be explained using bond enthalpies

Consider the reaction

Bond configuration for above reaction:

Each bond has certain H*

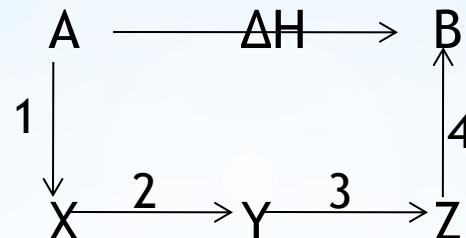

O=O -414 kJ, C=O -498 kJ, O-H -741 kJ, C-H -464 kJ

$$\Delta H^\circ = \Delta H^*(\text{bonds made}) - \Delta H^*(\text{bonds broken})$$

$$\Delta H^\circ = 2*(-498) + 4(-741) - 2(-414) - 4(-464) = -686 \text{ kJ}$$

Hess' Law and its applications

Enthalpy change accompanying a chemical reaction is the same whether it takes place in one or several stages since enthalpy is a state function

$$\Delta H^\circ = \Delta H^\circ(1) + \Delta H^\circ(2) + \Delta H^\circ(3) + \Delta H^\circ(4)$$

<u>Reaction</u>	<u>Enthalpy change</u>
$A \rightarrow X$	$\Delta H^\circ(1)$
$X \rightarrow Y$	$\Delta H^\circ(2)$
$Y \rightarrow Z$	$\Delta H^\circ(3)$
<u>$Z \rightarrow B$</u>	<u>$\Delta H^\circ(4)$</u>
$A \rightarrow B$	ΔH°

Hess' law is useful for calculating the unknown enthalpy change of a reaction using known reactions

Hess' Law and its applications

Example - Calculate the standard enthalpy of formation of solid Fe_3O_4 from the following enthalpy data

$$\Delta H^\circ_{298} = -264500 \text{ J}$$

$$\Delta H^\circ_{298} = -292500 \text{ J}$$

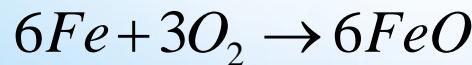

$$\Delta H^\circ_{298} = -230650 \text{ J}$$

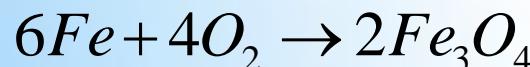

Main Reaction

Add the reactions in the following order to obtain the net reaction

Net reaction:

$$\Delta H = 6 \Delta H_1 + 3 \Delta H_2 - \Delta H_3$$

$$\Delta H/2 = -1117240 \text{ J/mole}$$

Example -

Calculate ΔH for the reaction $C_2H_4(g) + H_2(g) = C_2H_6(g)$, from the following data

Example -

Calculate ΔH for the reaction $4 \text{ NH}_3(\text{g}) + 5 \text{ O}_2(\text{g}) = 4 \text{ NO}(\text{g}) + 6 \text{ H}_2\text{O}(\text{g})$, from the following data

Isothermal enthalpy change for reactions not occurring at 298 K

Consider a general reaction with components at the same temperature different than 298 K:

ΔH°_{298} are tabulated for components

$$\Delta H = c\Delta H_C + d\Delta H_D - a\Delta H_A - b\Delta H_B$$

$$\left(\frac{\partial H}{\partial T} \right)_P = C_P \quad \frac{d\Delta H}{dT} = c \frac{dH_C}{dT} + d \frac{dH_D}{dT} - a \frac{dH_A}{dT} - b \frac{dH_B}{dT}$$

$$\left(\frac{\partial \Delta H}{\partial T} \right)_P = \Delta C_P = cC_{PC} + dC_{PD} - aC_{PA} - bC_{PB}$$

$$\boxed{\Delta C_P = \sum C_{P(\text{prod.})} - \sum C_{P(\text{react.})}}$$

Isothermal enthalpy change for reactions not occurring at 298 K

ΔH values for chemical reactions can be determined from ΔH°₂₉₈ values:

$$\int_{\Delta H_{298}}^{\Delta H_T} d\Delta H = \int_{298}^T \Delta C_P dT$$

$$\Delta H_T - \Delta H_{298}^o = \int_{298}^T \Delta C_P dT \quad \text{Kirchoff equation}$$

ΔH_T can also be calculated from the enthalpy increment equations:

$$\Delta H_T = \Delta H_{298}^o + \sum (H_T - H_{298})_{prod.} - \sum (H_T - H_{298})_{react.}$$

Example - Find the net heat available or required when the following reaction takes place at 800 K

Substance	ΔH_{298}^o (kJ/mole)	C_p (J/mole K)
CaO(s)	-634.3	$49.62 + 4.52 \times 10^{-3}T - 6.95 \times 10^5 T^{-2}$
CO ₂ (g)	-393.5	$44.14 + 9.04 \times 10^{-3}T - 8.54 \times 10^5 T^{-2}$
CaCO ₃ (s)	-1206.7	$104.52 + 21.92 \times 10^{-3}T - 25.94 \times 10^5 T^{-2}$

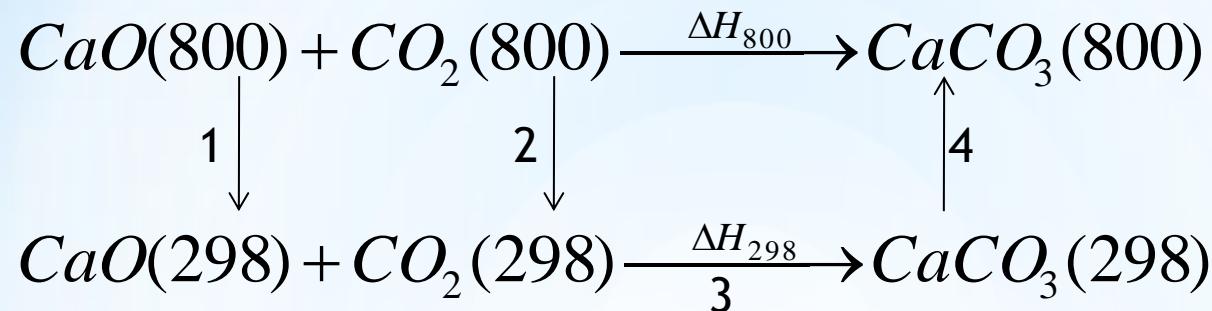

$$\begin{aligned}\Delta H_{298}^o &= \Delta H_{298}^o(CaCO_3) - \Delta H_{298}^o(CaO) - \Delta H_{298}^o(CO_2) \\ &= -1206.7 - 634.3 + 393.5 = -178.9 \text{ kJ}\end{aligned}$$

$$\begin{aligned}\Delta C_p &= C_{P(CaCO_3)} - C_{P(CaO)} - C_{P(CO_2)} \\ &= 10.76 + 8.36 \times 10^{-3}T - 10.45 \times 10^5 T^{-2} \text{ J/K}\end{aligned}$$

$$\Delta H_{800}^o = -178900 + \int_{298}^{800} (10.76 + 8.36 \times 10^{-3}T - 10.45 \times 10^5 T^{-2}) dT$$

$$\Delta H_{800}^o = -178900 + 5505 = -173395 \quad \text{J}$$

Alternatively ΔH_T can be calculated from Hess' law

$$\Delta H_1 = \int_{800}^{298} C_{P(CaO)} dT$$

$$\Delta H_2 = \int_{800}^{298} C_{P(CO_2)} dT$$

$$\Delta H_3 = \Delta H_{298}^o$$

$$\Delta H_4 = \int_{298}^{800} C_{P(CaCO_3)} dT$$

$$\Delta H_T = \Delta H_1 + \Delta H_2 + \Delta H_3 + \Delta H_4$$

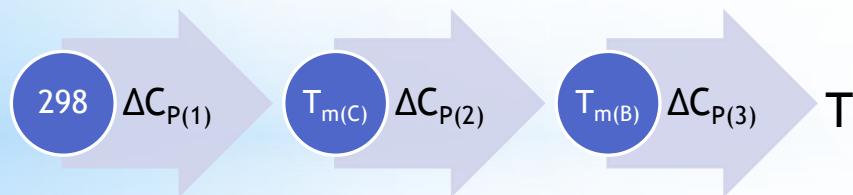

Isothermal enthalpy change involving phase change

Consider a general reaction with components at the same temperature different than 298 K where liquid B and C phases are solid at 298 K:

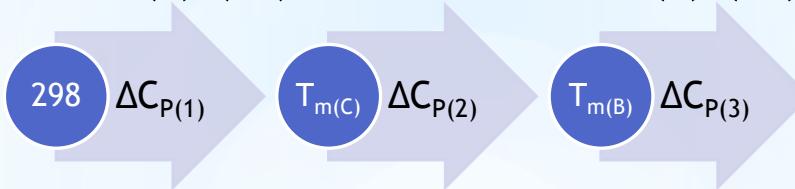

Kirschoff equation can be used to calculate ΔH°_T :

$$\Delta H_T = \Delta H_{298}^o + \int_{298}^T \Delta C_P dT$$

Component C transforms to liquid at $T_{m(C)}$
Component B transforms to liquid at $T_{m(B)}$
 ΔC_P separated into 3 ranges

Isothermal enthalpy change involving phase change

$$\Delta C_P^I = cC_{P(C(s))} + dC_{P(D(s))} - aC_{P(A(s))} - bC_{P(B(s))}$$

$$\Delta C_P^{II} = cC_{P(C(l))} + dC_{P(D(s))} - aC_{P(A(s))} - bC_{P(B(s))}$$

$$\Delta C_P^{III} = cC_{P(C(l))} + dC_{P(D(s))} - aC_{P(A(s))} - bC_{P(B(l))}$$

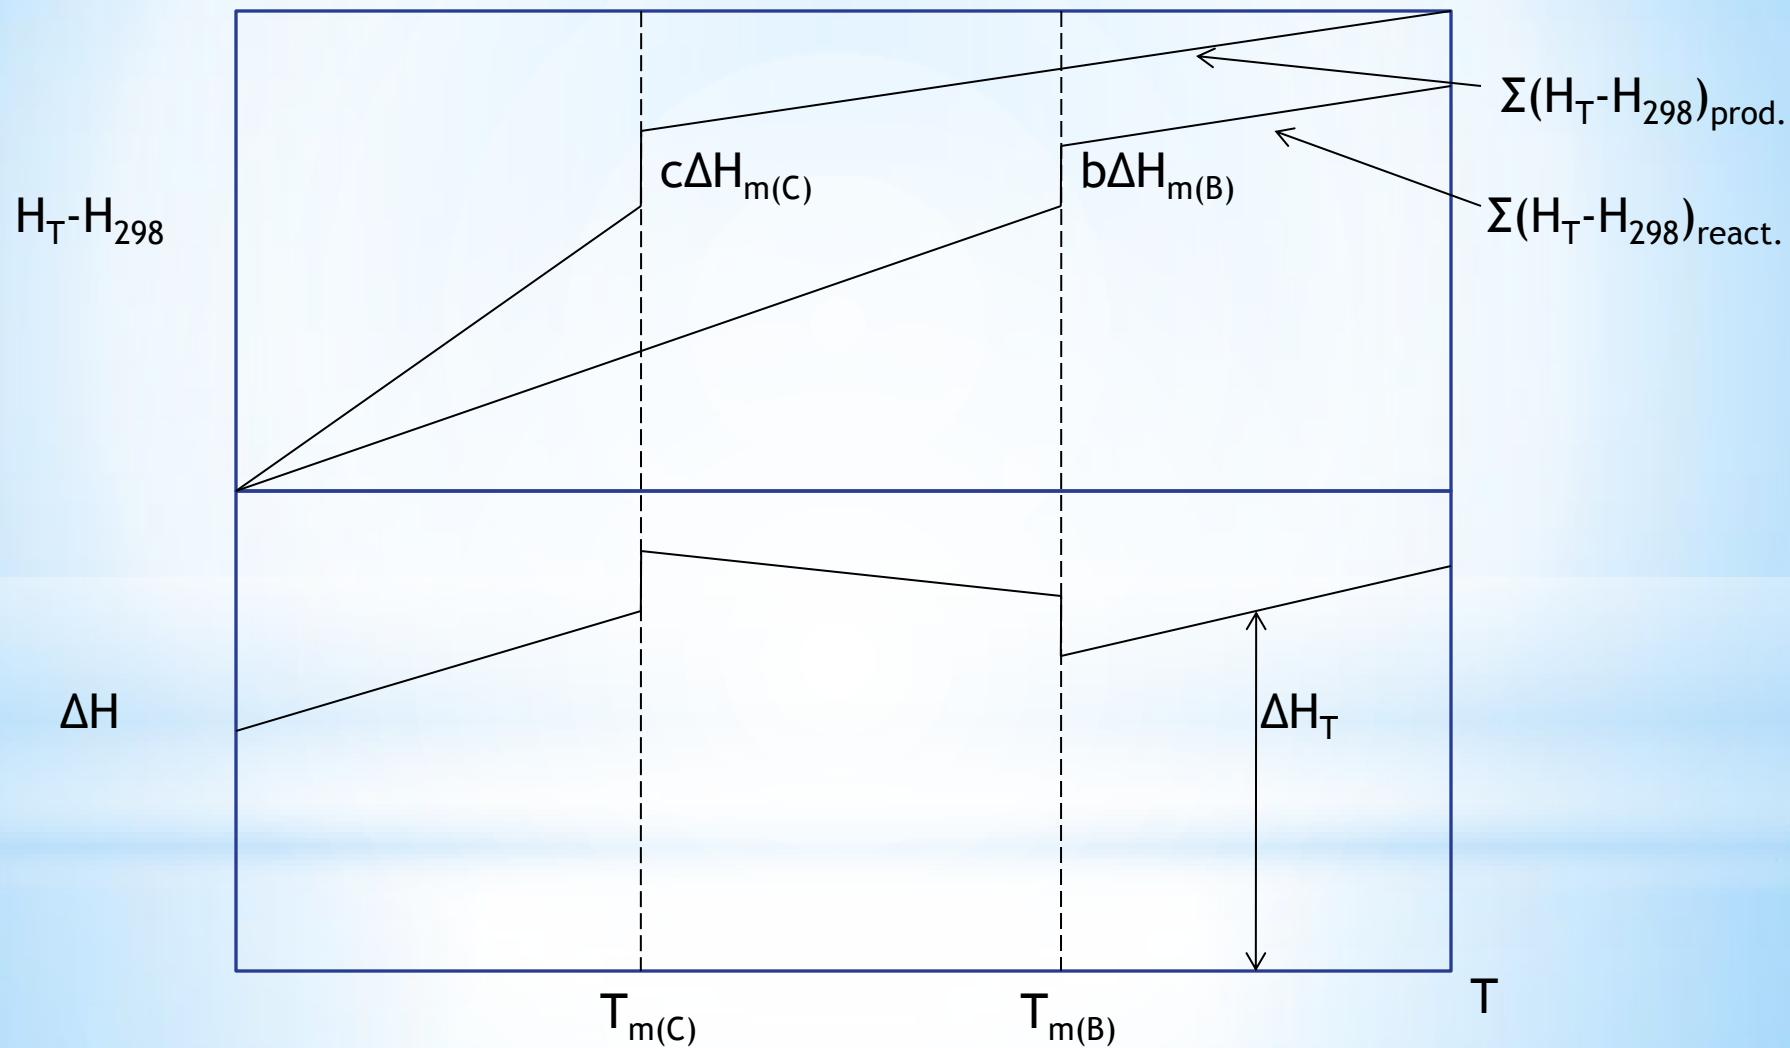

Therefore

$$\Delta H_T = \Delta H_{298}^o + \int_{298}^{T_{m(C)}} \Delta C_P^I dT + c\Delta H_{m(C)} + \int_{T_{m(C)}}^{T_{m(B)}} \Delta C_P^{II} dT - b\Delta H_{m(B)} + \int_{T_{m(B)}}^T \Delta C_P^{III} dT$$

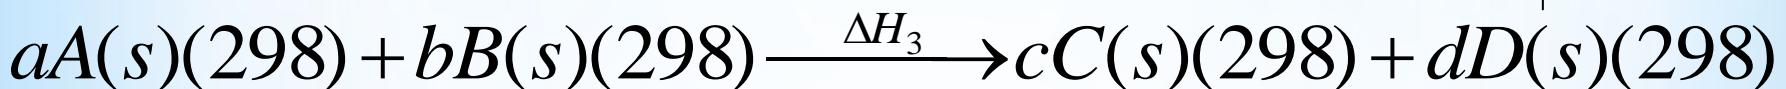

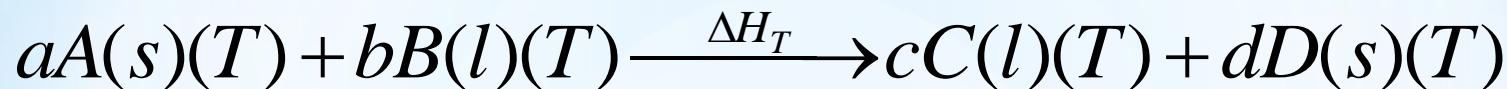

Since $H_T - H_{298}$ enthalpy increment equations incorporate phase changes,

$$\Delta H_T = \Delta H_{298}^o + \sum (H_T - H_{298})_{prod.} - \sum (H_T - H_{298})_{react.}$$

Isothermal enthalpy change involving phase change

Another alternative method that can be used in enthalpy computations for chemical reactions that involve phase transformations is the application of Hess' law

$$\Delta H_T = \Delta H_1 + \Delta H_2 + \Delta H_3 + \Delta H_4 + \Delta H_5$$

$$\Delta H_1 = a \int_T^{298} C_{P(A(s))} dT$$

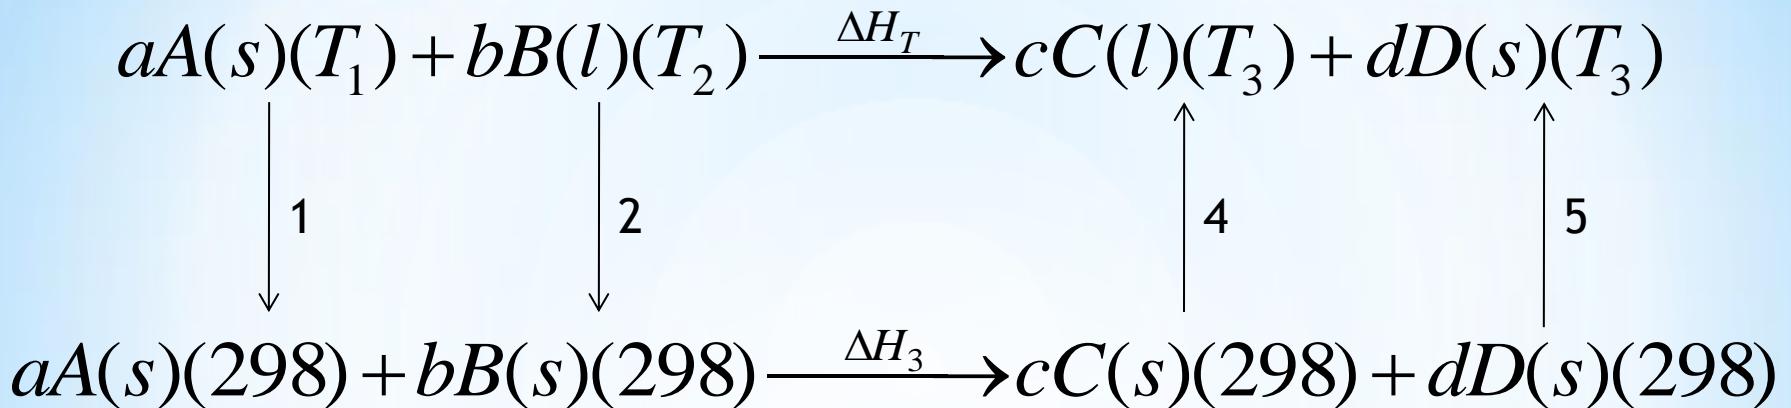

$$\Delta H_2 = b \left[\int_T^{T_{m(B)}} C_{P(B(l))} dT - \Delta H_{m(B)} + a \int_{T_{m(B)}}^{298} C_{P(B(s))} dT \right]$$

$$\Delta H_3 = \Delta H_{298}^o$$

$$\Delta H_4 = c \left[\int_{298}^{T_{m(C)}} C_{P(C(s))} dT - \Delta H_{m(C)} + a \int_{T_{m(C)}}^T C_{P(B(l))} dT \right]$$

$$\Delta H_5 = d \int_{298}^T C_{P(D(s))} dT$$

Non-isothermal chemical processes

$$\Delta H_T = \Delta H_1 + \Delta H_2 + \Delta H_3 + \Delta H_4 + \Delta H_5$$

$$\Delta H_1 = a \int_{T_1}^{298} C_{P(A(s))} dT = -a(H_{T_1} - H_{298})_{A(s)}$$

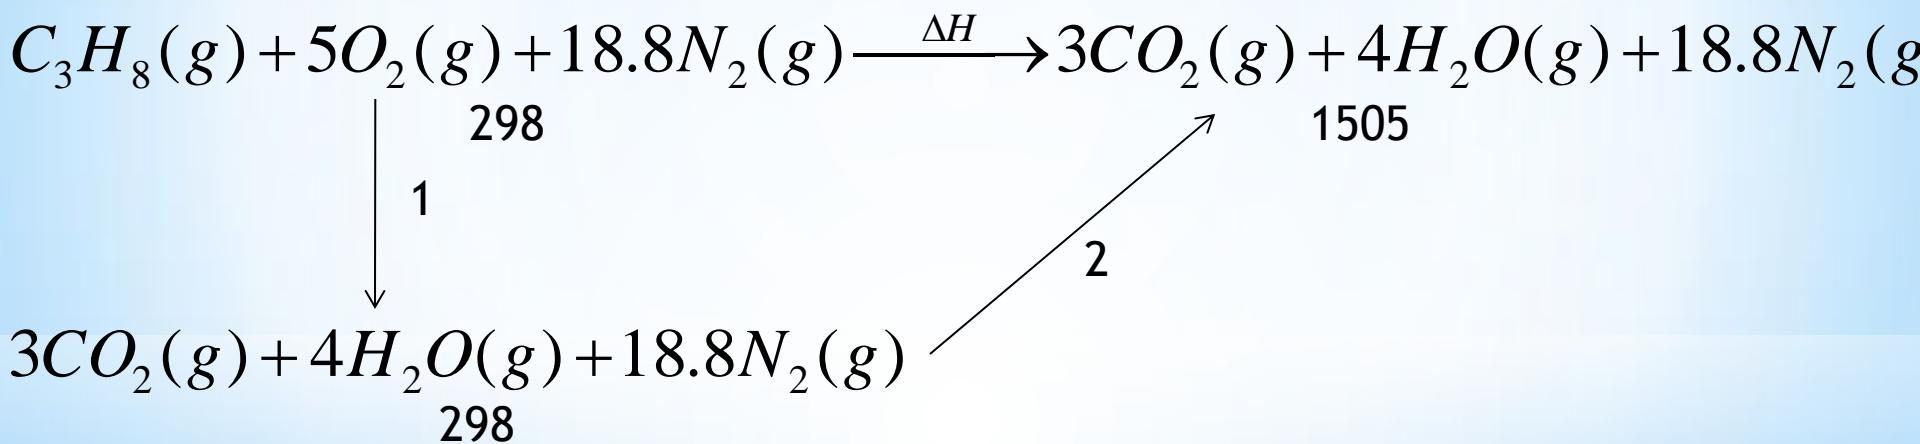

$$\Delta H_2 = b \left[\int_{T_2}^{T_{m(B)}} C_{P(B(l))} dT - \Delta H_{m(B)} + a \int_{T_{m(B)}}^{298} C_{P(B(s))} dT \right] = -b(H_{T_2} - H_{298})_{B(l)}$$

$$\Delta H_3 = \Delta H_{298}^o = \sum H_{298(\text{prod.})}^o - \sum H_{298(\text{react.})}^o$$

$$\Delta H_4 = c \left[\int_{298}^{T_{m(C)}} C_{P(C(s))} dT + \Delta H_{m(C)} + a \int_{T_{m(C)}}^{T_3} C_{P(C(l))} dT \right] = c(H_{T_3} - H_{298})_{C(l)}$$

$$\Delta H_5 = d \int_{298}^{T_3} C_{P(D(s))} dT = d(H_{T_3} - H_{298})_{D(s)}$$

Example - A furnace that is designed to melt silver/copper scrap is to be fired with propane and air. The propane vapor mixes with dry air at 298 K. Flue gases are expected to exit the furnace at 1505 K under steady state conditions. How long will a 45.5 kg container of propane maintain the furnace temperature if heat is conducted through the brickwork at the rate of 10000 kJ/hour ?

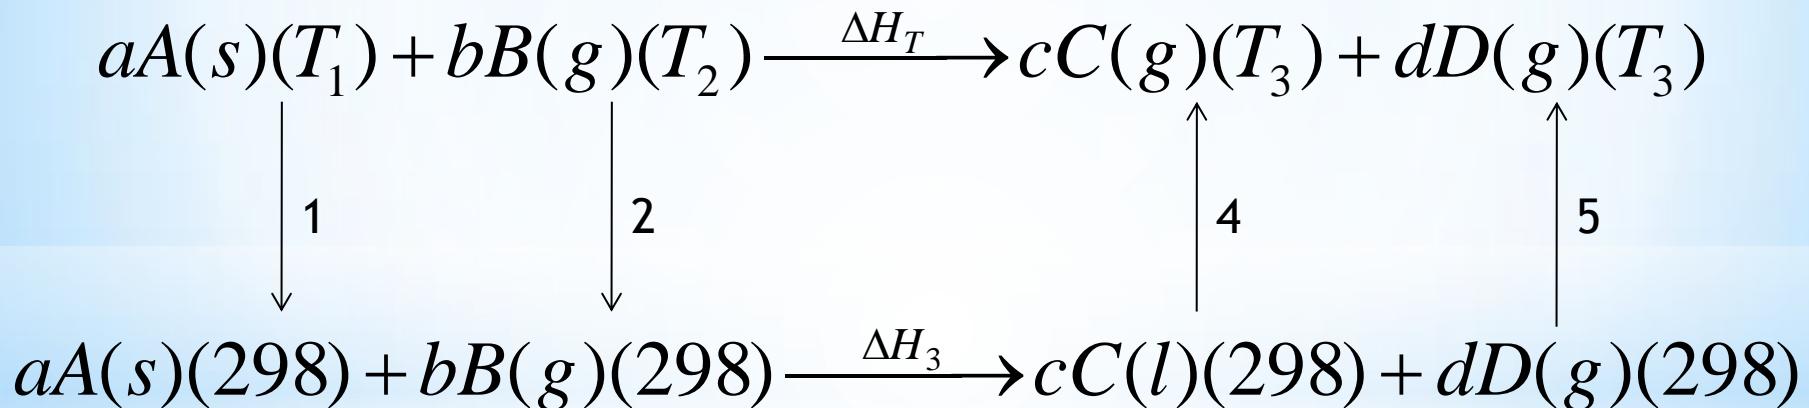

Substance	$H_T - H_{298}$ (J/mole)	ΔH_{298}° (kJ/mole)	C_p (J/mole K)
$C_3H_8(g)$		-103.55	
$CO_2(g)$	$-16476 + 44.25T + 0.0044T^2 + 8.62 \times 10^5 T^{-2}$	-393.5	$44.14 + 9.04 \times 10^{-3}T - 8.54 \times 10^5 T^{-2}$
$H_2O(l)$		-285.85	75.47
$H_2O(g)$	$34660 + 30.01T + 0.00536T^2 - 0.33 \times 10^5 T^{-2}$	-241.95	$30.01 + 10.72 \times 10^{-3}T + 0.33 \times 10^5 T^{-2}$
$N_2(g)$	$-8502 + 27.88T + 0.00213T^2$	--	$27.88 + 4.27 \times 10^{-3}T$
$\Delta H_v(H_2O)$	= 40897 J/mole		

Air: 21% O_2 + 79% N_2

Flame temperature

The maximum temperature the gaseous products can reach upon proceeding of an exothermic reaction is called the flame temperature

The furnace is considered as adiabatic for no heat loss to the surroundings and maximum flame temperature

$$\Delta H_1 + \Delta H_2 + \Delta H_3 = \Delta H_4 + \Delta H_5$$

$$\Delta H_4 = c \left[\int_{298}^{T_{m(C)}} C_{P(C(l))} dT + \Delta H_{v(C)} + a \int_{T_{m(C)}}^{T_{flame}} C_{P(C(g))} dT \right] = c(H_{T_{flame}} - H_{298})_{C(g)}$$

$$\Delta H_5 = d \int_{298}^{T_{flame}} C_{P(D(g))} dT = d(H_{T_{flame}} - H_{298})_{D(g)}$$

An adiabatic vessel contains 1000 grams of liquid aluminum at 700 °C. Calculate the moles of Cr₂O₃ which completely reduces chromium and raises the temperature of the resulting mixture of Al₂O₃(s) and Cr(s) to 1000 °C when added to the liquid aluminum. The initial temperature of Cr₂O₃ is 25 °C.

Chromium reduction reaction: Al(l) + Cr₂O₃(s) = Al₂O₃(s) + Cr(s) ,
